

Bulk RNA context after source-library qualification

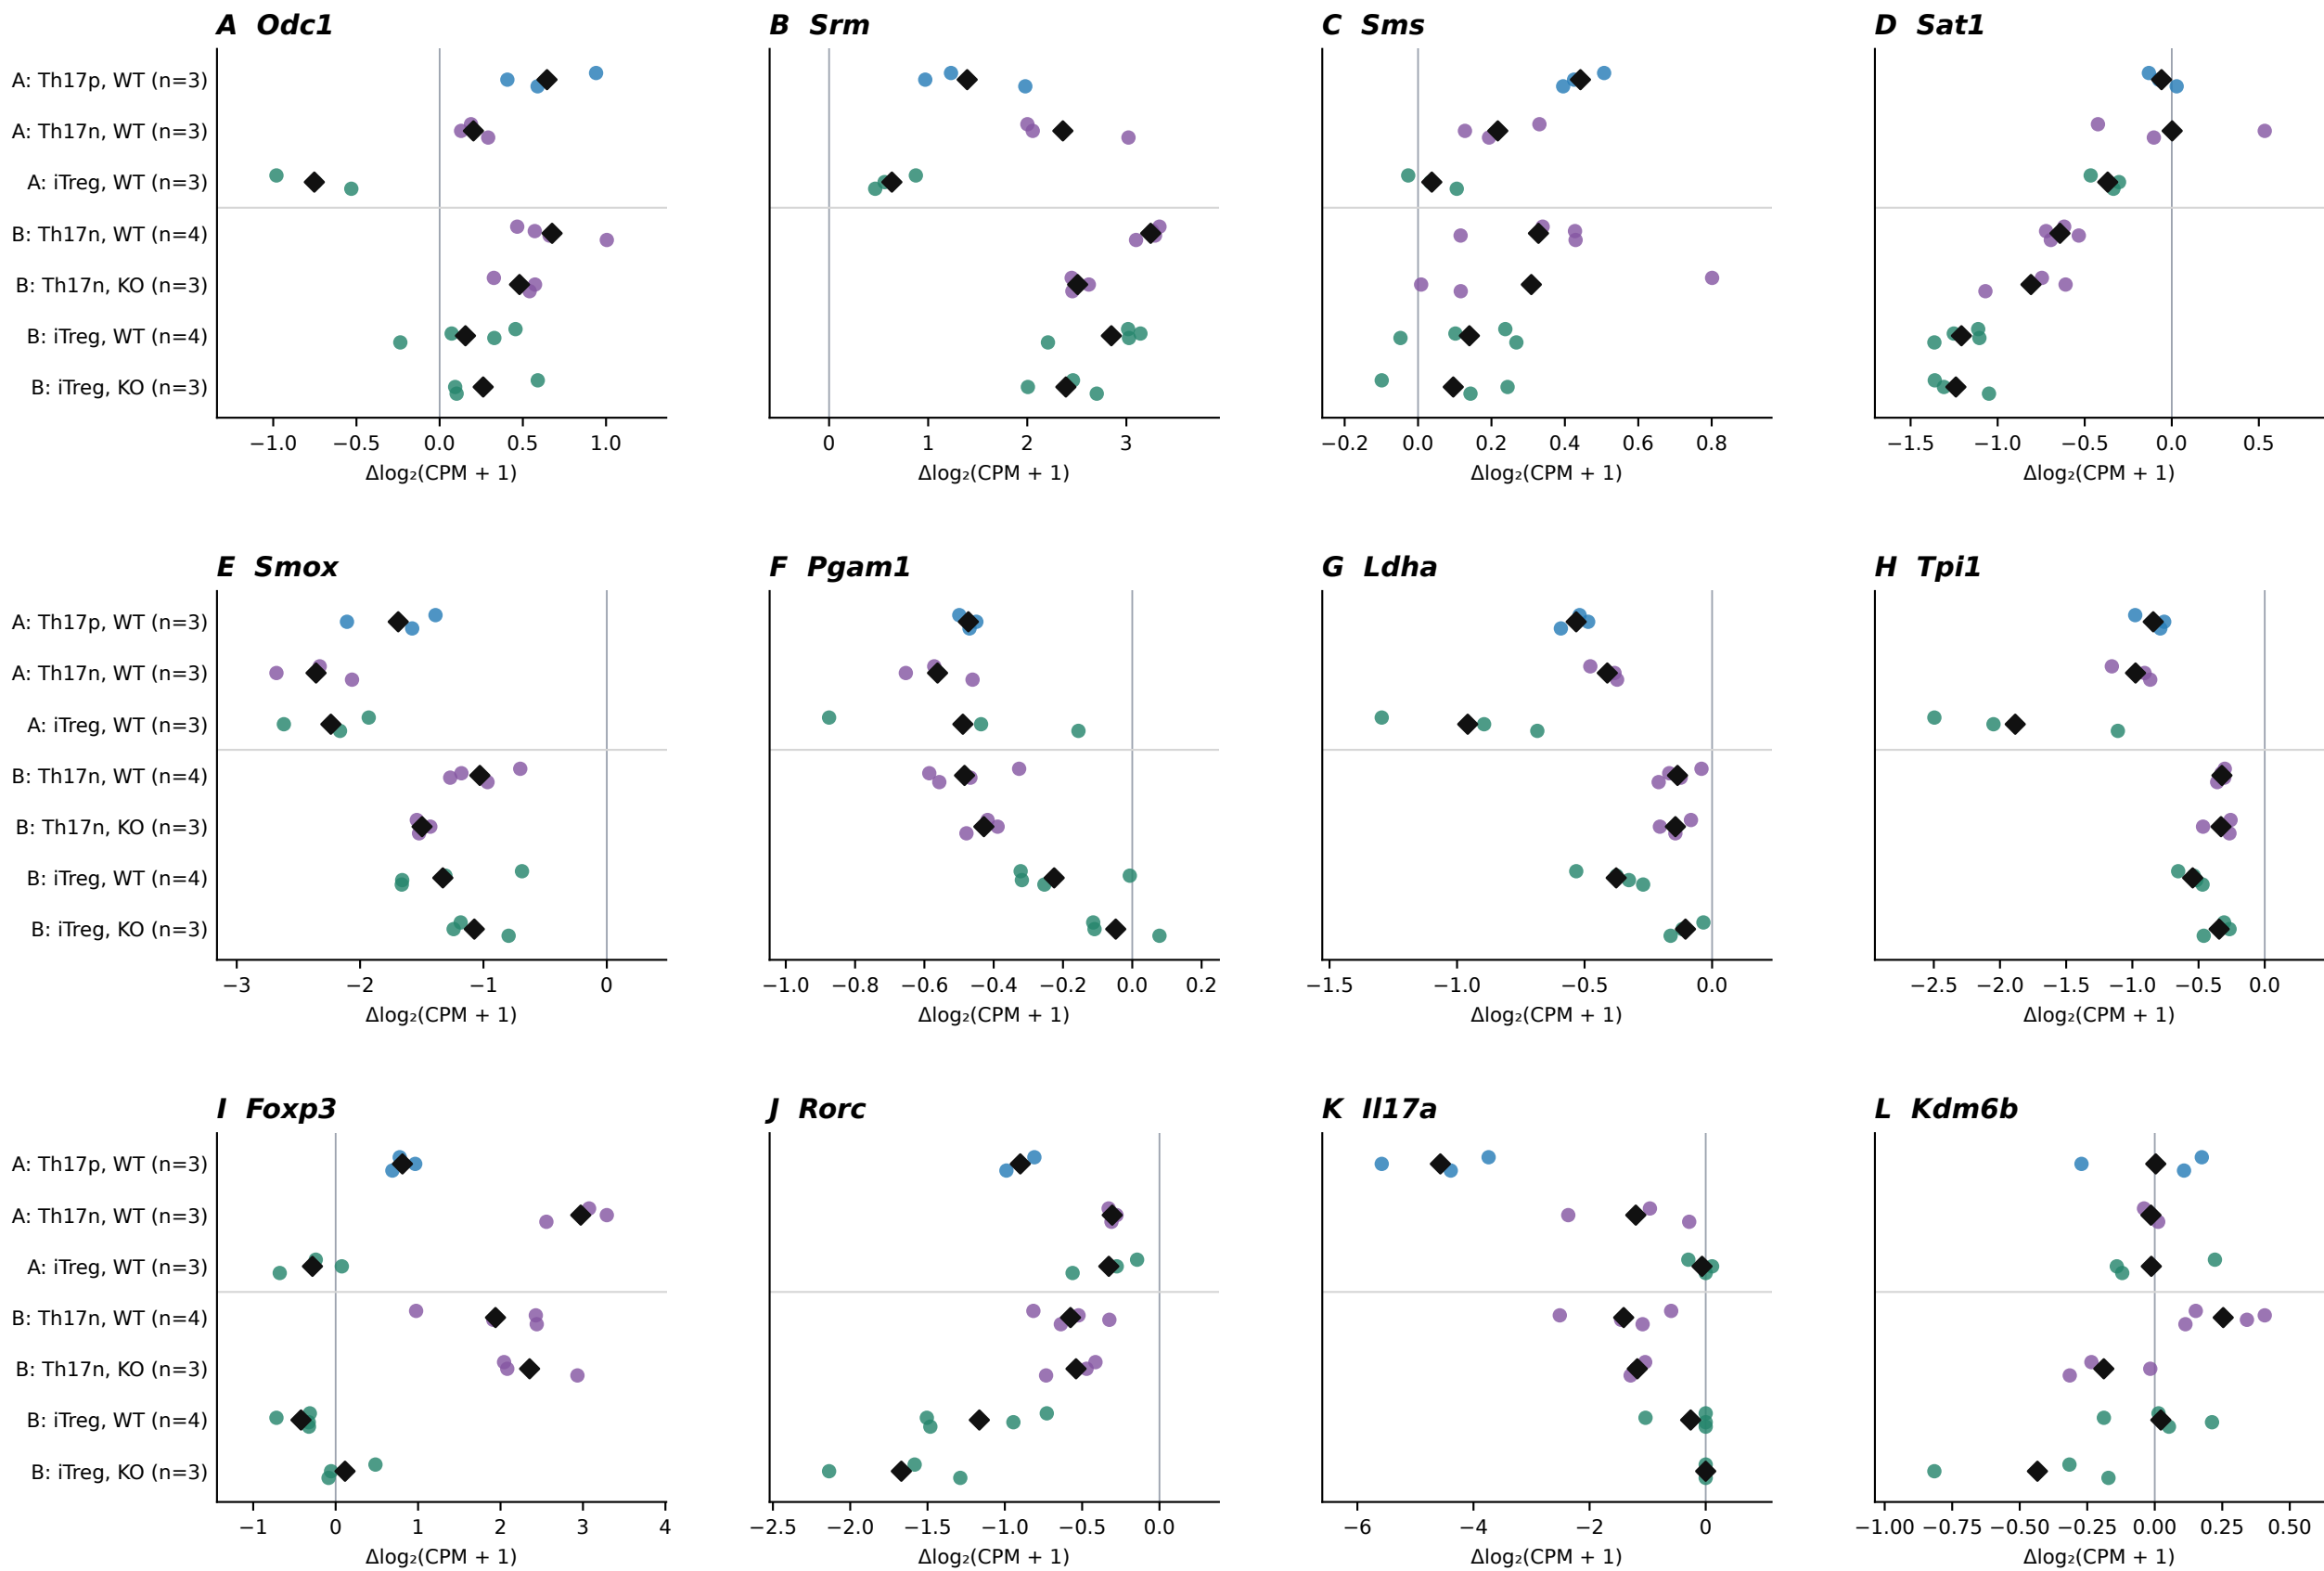

68-hour in-vitro mouse CD4 T-cell cultures | untreated control versus DFMO
PCA of all nonconstant deposited genes on $\log_2(\text{deposited-gene CPM} + 1)$

Lines connect paired cultures from the same source animal. Studies are analyzed separately; axes are not shared. No DEG-selected PCA or fate inference.

Prespecified genes: paired response to DFMO

Each circle is one source animal's DFMO – control difference; black diamonds are unweighted means. A = GSE162300 (3 WT); B = GSE162382 (4 WT, 3 JMJD3 KO). Lineages and genotypes remain separate. Endpoint: $\Delta\log_2(\text{deposited-gene CPM} + 1)$, 68-hour bulk RNA. No p values, DEG calls or biological importance cutoff.

Positive: greater normalized abundance after DFMO. Negative: lower after DFMO. Panel x-axis ranges differ. Counts from two technical runs are summed in A. Bulk abundance cannot separate within-cell change from selection, survival or mixture changes.
