

In Th17n, PGAM inhibition moves both gene groups, not the pro-inflammatory group alone

GSE290297 division-1 libraries | genes partitioned by the deposit's own DMSO Th17p-versus-Th17n contrast (BH ≤ 0.05 and $|\log_2 \text{FC}| \geq 1.5$), then plotted against each inhibitor

Dashed line: median shift of the 11,003 genes in neither group, the whole-transcriptome move each inhibitor produces; the numbers are each group's median after that shift is removed. Library-level descriptive contrasts on deposited TPM; no animal field exists, so none of this is animal-level inference. Group medians are post-hoc readouts of the governed table. Centring removes the global shift but does not make the groups independent.
