

PGAM keeps the published negative sign but is not the most distinctive reaction

Compass 1.0.0 on 60 micropools of Wp-R1 Th17n cells | version-and-input sensitivity, not Figure 1:
the published scVI-imputed input was never deposited and the scope is two RECON2 subsystems

Pools are not independent replicates and share animals and cultures, so the nominal degrees of freedom overstate the information. Compass scores are model outputs from RNA, not flux. Restricting the reaction set puts the published ~ 900 -reaction ranking out of scope. Ranks are the governed run's own tie-aware values, so tied reactions share a rank.
